Ferritin (L)  
KAMIYA BIOMEDICAL COMPANY

For the Quantitative Determination of Ferritin Levels in Serum and Plasma

Cat. No. KAI-046

INTENDED USE

The K-ASSAY® Ferritin assay is an in vitro diagnostic reagent for the quantitative determination of ferritin (an iron-storing protein) in human serum and plasma by immunoturbidimetric assay on the Roche / Hitachi 917 and other analyzers. Measurements of ferritin aid in the diagnosis of diseases affecting iron overload and iron deficiency anemia. FOR IN VITRO DIAGNOSTIC USE.

INTRODUCTION AND SUMMARY

Ferritin is an iron-containing protein with a molecular weight of approximately 450,000 daltons. It is found mainly in the human liver and spleen, where its function is to eliminate and store iron, and is also found in small amounts in human serum. Ferritin is decreased in iron deficiency anemia and increased in iron overload. Ferritin levels correlate with and are useful in the evaluation of total body storage iron.

The K-ASSAY® Ferritin is a latex-enhanced immunoturbidimetric assay, developed to accurately and reproducibly measure ferritin levels in serum and plasma samples.

PRINCIPLE OF TEST

When an antigen-antibody reaction occurs between ferritin in a sample and an anti-ferritin antibody, which has been sensitized to latex particles, agglutination occurs. This agglutination is detected as an absorbance change, with the magnitude of the change being proportional to the quantity of ferritin in the sample.

The actual concentration is then determined by interpolation from a calibration curve prepared from calibrators of known ferritin concentration.

KIT COMPOSITION

Reagents:
- Liquid stable
- R1: Buffer Reagent
- R2: Latex Suspension

Materials Required But Not Supplied:
- 0.07 w/v% suspension of latex particles sensitized with rabbit anti-human ferritin antibody.

WARNING AND PRECAUTIONS

FOR IN VITRO DIAGNOSTIC USE. Rx only.

Not to be used internally in humans or animals. Normal precautions exercised in handling laboratory reagents should be followed.

Do not mix or reuse reagents from one test kit with those from a different lot number.

Do not reagents past their expiration date stated on each reagent container label.

Do not pipette by mouth. Avoid ingestion and contact with skin.

Whole blood is collected in sodium EDTA or sodium heparin anticoagulant. After collection, immediately centrifuge. In the U.S., follow NCCLS guideline H3-A2. If the assay cannot be performed within 24 hours, then the sample should be tightly capped and frozen at -20°C. Avoid repeated freeze-thaw cycles. Samples should be thawed at room temperature in a water bath or air. Undiluted samples should be used for this assay.

Materials Supplied:
- KAI-046 Ferritin (L) Assay
- Reagent 1 (R1) Buffer Solution 2 x 41 mL
- Reagent 2 (R2) Latex Suspension 2 x 20 mL

PROCEDURE

Materials Required But Not Supplied:
- Calibrators: 100, 200, 500, 1,000 ng/mL
- Saline (0.9% w/v NaCl)
- Roche / Hitachi 917 or other chemistry analyzer

Assay Procedure

An example of automated application:

Sample 7 µL
↓  
- R1 (Buffer Reagent) 140 µL
  ↓ 37°C, 5 min.
- R2 (Latex Reagent)  70 µL
  ↓ 37°C, 5 min.

Rate, 600 nm (main) / 800 nm (sub)

Note: Allow all reagents and specimens to warm to room temperature. Mix all reagents gently before using.

SPECIMEN COLLECTION AND PREPARATION

Serum

Blood should be collected from a patient and the serum separated as soon as possible. Since the blood is drawn, it should be allowed to clot, centrifuged, and the serum separated from the clot tube. For highly turbid samples, it is recommended that the sample be spun and the lipid layer be removed. It is recommended that the specimen collection be carried out in accordance with the NCCLS document M29-A2. After sampling, the specimen should be immediately stored at 2-8°C and assayed as soon as possible. If the assay cannot be performed within 24 hours, then the sample should be tightly capped and frozen at -20°C. Avoid repeated freeze-thaw cycles. Samples should be thawed at room temperature in a water bath or air. Undiluted samples should be used for this assay.

Plasma

Whole blood is collected in sodium EDTA or sodium heparin anticoagulant. After collection, immediately centrifuge. In the U.S., follow NCCLS guideline H3-A2. If the assay cannot be performed within 24 hours, then the sample should be tightly capped and frozen at -20°C. Avoid repeated freeze-thaw cycles. Samples should be thawed at room temperature in a water bath or air. Undiluted samples should be used for this assay.

Quality Control

A five-point calibration curve should be made using the K-ASSAY® Ferritin Calibrator and saline (0 ng/mL). In our laboratory, the calibration curve was valid for at least 4 weeks. It is recommended that the user determine calibration frequency on their analyzer as the calibration curve stability may change due to analyzer condition and use. Calibration is recommended whenever a new lot of reagent is used or when quality control material is outside the specified range.

QUALITY CONTROL

A quality control program is recommended for all clinical testing laboratories. It is recommended that controls, both normal and abnormal, be run with each batch of samples to monitor the procedure. Each laboratory should establish its own control range by assaying the control a sufficient number of times to generate a valid mean and acceptable range.

CALCULATIONS

Ferritin levels are determined using the prepared calibration curve.
**LIMITATIONS OF PROCEDURE**

The measurable range for this ferritin test kit is between 2 ng/mL and 1,000 ng/mL. If the ferritin concentrations are greater than the highest calibrator value, dilute the sample with isotonic saline and re-assay. Multiply the result by the dilution factor to compensate for the dilution. Performance of this assay has only been evaluated on adult specimens. Since a reference range is only available for adult specimens, this assay should only be used for adults. Intra-fat concentrations greater than 3% have been shown to interfere with the assay, however, intra-lipid concentrations up to 5% do not interfere with the assay.

**PERFORMANCE**

**Recovery**

When a serum sample with a known ferritin value is assayed, the results obtained should be within ±8%.

**Precision**

(Within Run) Acceptance Criteria: When a sample is repeatedly assayed 10 times, the absorbance C.V. is less than 7%. Serum control samples were assayed 21 times on the same day.

**Accuracy / Correlation**

A comparison of the K-ASSAY® Ferritin and another company’s Ferritin on the Hitachi 917 was performed with the following results. Statistics were calculated by linear regression. Samples used in the correlation study were serum samples from Asian patients.

\[
y = 0.89x - 9.4037 \\
r = 0.997 \\
n = 64 \\
x = Company A’s Ferritin \\
y = K-ASSAY® Ferritin
\]

Slope 95% CI = ± 0.0177 (0.8723 to 0.9077) Y-Intercept 95% CI = ± 6.443 (15.8467 to –2.9608)

**EXPECTED VALUES**

226 normal male serum samples and 205 normal female serum samples were assayed for ferritin on a Roche/Hitachi 917 analyzer.

Male (n = 226): The reference range was 7-253 ng/mL
Female (n = 205): The reference range was 2-110 ng/mL

It is recommended that each laboratory establish its own expected range.
